Neural Network Formulation

- Fully connected feedforward network $f : R^N \rightarrow R^M$

- Fully connected feedforward network $f : R^N \rightarrow R^M$

$$y = f(x) = \sigma(W^L \cdots \sigma(W^2 \sigma(W^1 x + b^1) + b^2) \cdots + b^L)$$

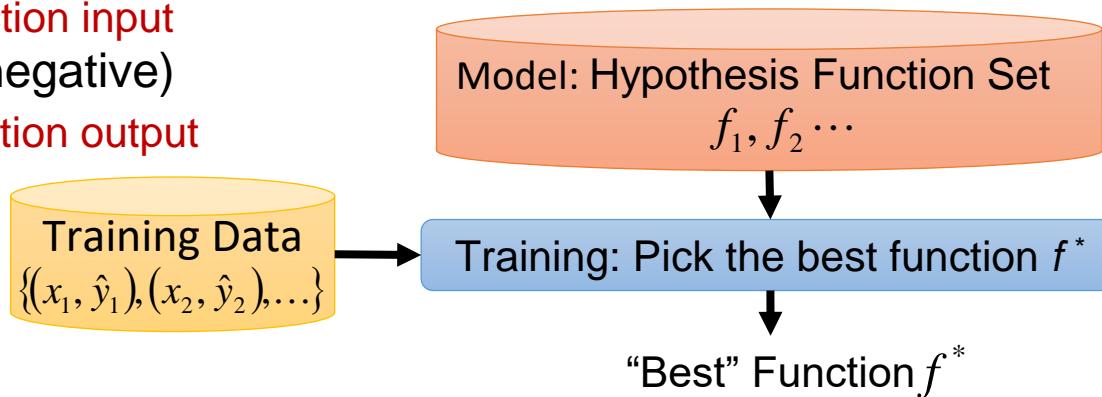

Loss Function for Training

x : “It claims too much.”

\hat{y} : - (negative)

function output

A “Good” function: $f(x; \theta) \sim \hat{y} \rightarrow \|\hat{y} - f(x; \theta)\| \approx 0$

Define an example loss function: $C(\theta) = \sum_k \|\hat{y}_k - f(x_k; \theta)\|$

sum over the error of all training samples

Computing the gradient includes millions of parameters.
To compute it efficiently, we use **backpropagation**.

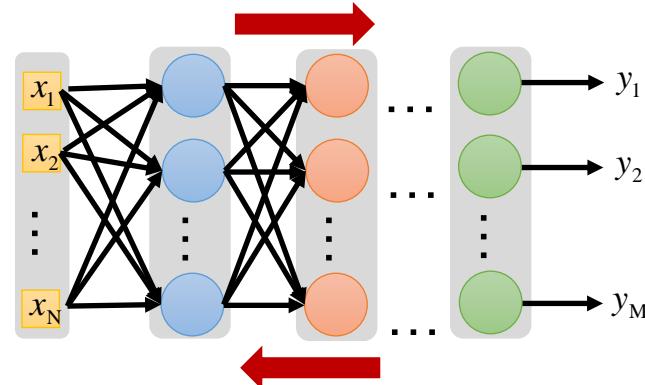

Backpropagation

如何有效率地計算大量參數呢？

Forward v.s. Back Propagation

- In a feedforward neural network

- forward propagation
 - from input x to output y information flows forward through the network
 - during training, forward propagation can continue onward until it produces a scalar cost $C(\theta)$
 - back-propagation
 - allows the information from the cost to then flow backwards through the network, in order to compute the **gradient**
 - can be applied to any function

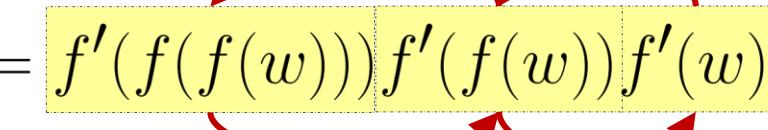

Chain Rule

$$\Delta w \rightarrow \Delta x \rightarrow \Delta y \rightarrow \Delta z$$

$$\frac{\partial z}{\partial w} = \frac{\partial z}{\partial y} \frac{\partial y}{\partial x} \frac{\partial x}{\partial w}$$

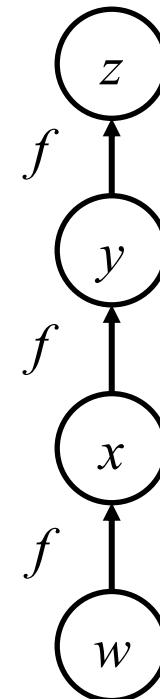

$$= f'(y) f'(x) f'(w)$$

forward propagation for cost

$$= [f'(f(f(w))))|f'(f(w))|f'(w)]$$

back-propagation for gradient
